

Background-

I work in masterschool. The company has Maestro which is ai university and ai college with real students who are getting real degrees recognized by the u.s government. the students in the university/college learn with maestro software. it's a software where the company pre-loaded prompts for each lesson(a few lessons together are an official course students are taking in maestro university/college), and the llm's that power maestro software, for each student each lesson, building a lesson and every time in the lesson teach the student something, ask him question/questions, continue teaching and continue asking (of course also give answers and explain the answers) until the llm decides the mastery goals for this lesson accomplished and then they continue to next lesson. Most of the students come from low social economic status bc today the business model is students get the degree for free, and masterschool get their money from the government from the budgets that is designated for the students higher education. Currently masterschool do only business management and computer science degrees, and only in the u.s and only around 7,000 students, and they on their way to expand to more countries and more fields of degrees, in order to get to many more students. Most of the students study with their phones, few of them with laptops.

Now the problem-

Masterschool want to get to many more students with version that will cost 0\$ or close to it per user to masterschool. They want to create a product that will get to many many user, they'll like it and then some of them will join the masterschool university and masterschool will get the government funding for them. The problem is the llm cost are very big, so this 0\$ product can't rely on that. I'm a software engineer in masterschool on hackathon and I need to tackle that problem.

Research need to be done –

1. which models we should use? We can take 2 approach – a. ask the user what is phone is and give him model that fits him, or just use a model that will fit most students. Anyway we need to make research about the models is ideal for this task

More points-

- a. it's competition with 7 other juniors software engineers like my self. I need to honestly think what they'll do and what can make my solution the winner
- b. we need to think of something great that will bring true value to the company.

c. we need to analyze what are the core problems we're dealing with and look at other places where this problem was solved by other people.
